

Most productivity tools assume you'll remember to use them.

Prefrontal doesn't. It watches your context — location, calendar, time of day, recent activity — decides on its own when to speak up, and nudges through the channel you'll actually notice. Then it learns from whether the nudge *worked*. **It gets better the longer you use it.**

🧠 Learns from what worked

Not another to-do list — a model of you.

👉 One tap, or it fails

If logging is harder than ignoring, it's useless.

🔒 Your data stays home

Nothing leaves your network unless you say so.

✓ WHAT IT DOES TODAY — LIVE, WITH A CONCRETE EXAMPLE

🕒 Departure reminders

"2:14 — leave in 6 min for the 2:45 dentist. Traffic's heavy."

Factors in real traffic, then escalates **push** → **sound** → **phone call** until you answer. **On time, no nagging.**

🔔 Nudges that decide themselves

It picks the moment, the words, and the channel — and you tap "Wrap up" or "I'm back" right from the lock screen.

A coaching engine, quiet hours and all. **A coach, not an alarm clock.**

📱 Panic mode

Frozen? One tap → what's actually on fire, what to ignore, and one 5-minute first step.

Just where to put your hands next — not the whole plan. **Breaks the freeze.**

🎯 Hyperfocus guard

Three hours down a rabbit hole? A gentle check. Deep in the right thing? It shields you from every other ping.

Protects good focus, interrupts the costly kind.

✅ The right task, right now

"20 min free at 4pm — knock out 'call the pharmacy.'" Short, low-energy, and the thing you keep dodging.

Matches effort to your energy and the clock. **Not a guilt-list.**

💬 Edit your day in plain English

"Bump the dentist call to urgent and drop the dry cleaning." — Done.

Type it how you'd say it; it previews, you confirm. **No forms.**

ALSO LIVE → Mail triaged to a short action list

Morning briefing

Bad-day recovery mode

One-tap lock-screen replies (ntfy)

Multiple users, each learns on their own

It quietly learns → your **real** departure lag, **which reminders you ignore after 3pm**, when you tend to go quiet, how much you underestimate time — and tunes its timing, wording, and channel to **you**. Miss a reminder? That's data too.

→ WHERE IT'S GOING NEXT

→ **Context Packs.** Role-based bundles — *Parent, Caregiver, New job* — that pre-wire the primitives for a whole life situation.

→ **One intake for everything.** Mail, a calendar change, a quick thought — captured, sorted, and routed the same way.

→ **First-class delivery.** Native Pushover / ntfy / TTS publishing (today it routes through n8n).

→ **Shared co-parent sheet.** One household sheet both parents edit in plain English — sizes, appts, behavior plans — to balance the invisible load.

→ **Sharper learning.** Per-situation time drift, learned channel response, tuned quiet hours.

→ **Live lock-screen timer.** A real countdown for an active outing, in the Dynamic Island.

⚙️ UNDER THE HOOD — FOR THE CURIOUS

A system of small, single-purpose agents over a **local SQLite behavioral memory** — the core everything learns into. **Capture** → **triage** → **memory** → **coaching** → **delivery**. A **coaching tick engine** asks each module "anything due?" and picks the channel; a **FastAPI** surface takes one-tap input from **iOS Shortcuts**; **n8n** orchestrates; **Ollama** runs inference on-device (optional **Claude** per task); reminders escalate over **Pushover** / **ntfy** / **TTS** with one-tap action buttons; everything's reachable over **Tailscale**, multi-user. Switch on only the ADHD modules that fit your profile.

Python 3.10+

The modules

One executive-function challenge each — a primitive aimed at a specific dysfunction.

Switch on only what fits you

Each module is opt-in, per user

All five are live today

ADHD isn't one thing — so Prefrontal isn't one nudge.

Executive function fails in distinct ways: you lose the feel of time, you can't start, you can't stop, you switch on impulse. Each module targets *one* of those failure modes with its own trigger and its own intervention — built on the same shared behavioral memory, so they learn together.

Why split it up?

A single "reminder" can't tell paralysis from hyperfocus. Naming the dysfunction lets each response be the right one.

SOON

planned

Time perception & estimation

🕒 Time Blindness

time_blindness

Difficulty **sensing elapsed time and estimating duration** — chronic underestimation of how long tasks and travel really take, and departures that slip late.

HOW IT SHOWS UP

"Five more minutes" becomes forty; you leave for the 2:45 appointment at 2:40 because it feels close.

WHAT PREFRONTAL DOES

Corrects your estimates from your real history, **pads departures** with a learned buffer, and **calls out elapsed time** mid-task **SOON**.

Task initiation

📁 Task Paralysis

task_paralysis

Difficulty **initiating tasks despite intent** — the work stalls before it ever begins, especially when it's large or ambiguous.

HOW IT SHOWS UP

You know exactly what to do and still can't start; the draft sits open, untouched, for an hour.

WHAT PREFRONTAL DOES

Shrinks it to a **5-minute first step**, **auto-decomposes** the big/vague thing into moves, and offers a **body-double check-in**.

Focus regulation

🎯 Hyperfocus

hyperfocus

Intense sustained focus — a **strength when aimed right**, a **liability when misdirected** or when it overruns basic needs and commitments.

HOW IT SHOWS UP

Three hours into a side rabbit-hole; the real deadline and lunch both slid by unnoticed.

WHAT PREFRONTAL DOES

Protects the window when focus is on-target, **checks alignment** when it may be off, enforces **biological breaks**, and **auto-closes** abandoned sessions.

Response inhibition

⚡ Impulsivity

impulsivity

Acting before reflecting — **abrupt context switches and snap decisions** that pull attention off the intended task.

HOW IT SHOWS UP

A ping pulls you into a new tab, then a chore, then something else — the original task never comes back.

WHAT PREFRONTAL DOES

Inserts a **reflective pause** before a snap switch, **captures the distraction to defer** it, and **surfaces your switch rate** **SOON**.

Prospective memory, out in the world

📍 Location-Aware Task Anchor

location_anchor

Leaving with a short, stated intention and **losing track of time in the field** — errands that quietly stretch well past when you meant to be back.

HOW IT SHOWS UP

"Just running to the store" turns into a two-hour loop of unplanned stops.

WHAT PREFRONTAL DOES

Escalating field nudges — **soft** at your stated time, **firm** when you're over, a **voice call** if you go far past — all **gated** by actually being on-site.

Same primitive, five aims — **each module names the dysfunction it treats**.

Opt-in per user • shared memory • learns which nudge works for you
